

Flask Random Joke API

Introduction

This project is a simple web application built using **Flask**. It connects to an external joke service and fetches random jokes from the internet. The application sends a request to the Joke API and returns the joke to the user.

Libraries Used

Flask – Used to create the web application and manage routes.

Requests – Used to send HTTP requests to the JokeAPI and receive data.

Functions / Routes

home() – Loads the main webpage using an HTML template.

get_joke() – Sends a request to the Joke API, processes the response, and returns a random joke.

Working

When the user opens the website, the home page loads. When the **/joke** route is accessed, the program requests a random joke from the API and displays it to the user.

Conclusion

This project demonstrates how Flask can interact with external APIs to fetch and display dynamic data such as random jokes.
